1 Introduction

Modbus is a widely-used serial communication protocol in industrial automation, designed to transmit data over serial lines such as RS-232 and RS-485, and also over Ethernet (Modbus TCP/IP).

The device that requests the information is called a “master” while devices that give the requested information are called “slaves”. A single master device communicates with multiple slave devices, initiates queries and receives responses.

Modbus is valued for its simplicity and reliability, with a straightforward message structure that includes an address field, function code, data field, and an error check field. Its open protocol nature promotes interoperability between devices from different manufacturers.

1.1 To connect

All SAVE ventilation units have a standard and readily available Modbus/RTU connection on the connection board marked A(+), B(-), GND.

Alternative Modbus/TCP connection can be made over TCP/IP with use Modbus RTU to TCP gateway accessory (item number: 454345).

Table 1 Modbus connection information

Slave address: 1 to 247 (default setting is 1)
Baud Rate: 9600 to 115200 (default setting is 115200)
Parity: None, Even, Odd (default setting is None)
Stop Bits: 1 (fixed value)

Parameters can be changed in the SAVE TOUCH control panel: **Service** ➢ **Communication** ➢ **Modbus**.

1.2 Transmission modes

Input registers (read-only) and Holding registers (read-write) are supported in Modbus protocol.

All registers are 16 bit integers.

Table 2 Register types used

Input Registers	IR	16-bit quantity, analog Input Register provided by an I/O system, read-only, Modbus Function 04
Holding Registers	HR	16-bit quantity, analog output Holding Register can be changed by an application program, read-write, Modbus function 03 / 06 / 16

1.3 Value calculations

To calculate the remaining or passed time:

- Time = (65535 * **TIME_H*) + **TIME_L*

Note:

Example:

REG_USERMODE_REMAINING_TIME_L = 61981

REG_USERMODE_REMAINING_TIME_H = 3

Remaining user mode time = (65535 * 3) + 61981 = 258586 seconds

To calculate the date, timestamp date:

- Time seconds = (65536 * *TIME_H*) + *TIME_L*

  Constant = 760516096
- Days from 1970-01-01 = (Time seconds - Constant) / 86400

  Date (GMT+0) = 1970-01-01 + Days from 1970-01-01

Note:

Example:

**TIME_L* = 28296

**TIME_H* = 37819

Time seconds = (65536 * 37819) + 28296 = 2478534280

Days from 1970-01-01=(2478534280 - 760516096) / 86400 = 19884,47

Date (GMT+0) = 1970-01-01 + 19884,47 = 2024-06-10 11:16:24

To calculate the temperature value:

- If the sensor reading is higher than 60000:
  Value = (*SENSOR_VALUE* - 65536) / 10
- If the sensor reading is lower than 60000:
  Value = *SENSOR_VALUE* / 10

Note:

Example:

REG_SENSOR_OAT = 20

REG_SENSOR_OAT = 20 / 10 = 2 °C

1.4 Limitations

Do not to exceed 200 000 writes to Modbus registers.

When this limit is exceeded:

1. Saved data in memory is no longer reliable and can be corrupted.
2. After SAVE ventilation unit power on the Modbus register values will return to the last reliable data. Factory settings are restored if there is no reliable data on memory.
